

Laboratory 2

Expected delivery of lab_02.zip must include:

- program_2.s and program_3.s
- This file, filled with information and possibly compiled in a pdf format.

Please, configure the winMIPS64 simulator with the *Base Configuration* provided in the following:

- Code address bus: 12
- Data address bus: 12
- Pipelined FP arithmetic unit (latency): 6 stages
- Pipelined multiplier unit (latency): 8 stages
- divider unit (latency): not pipelined unit, 24 clock cycles
- Forwarding is enabled
- Branch prediction is disabled
- Branch delay slot is disabled
- *Integer ALU: 1 clock cycle*
- *Data memory: 1 clock cycle*
- *Branch delay slot: 1 clock cycle.*

- 1) Write an assembly program (**program_2.s**) for the *winMIPS64* architecture described before able to implement the following piece of code described at high-level:

```
for (i = 0; i < 30; i++){  
    v5[i] = (v1[i]*v2[i]) + v3[i];  
    v6[i] = (v3[i]*v4[i])/v5[i];  
}
```

Assume that the vectors `v1[]`, `v2[]`, `v3[]`, and `v4[]` are allocated previously in memory and contains 30 double precision floating point values; **assume that v5[] will not contain 0 values**. Additionally, the vectors `v5[]`, `v6[]` are empty vectors also allocated in memory.

- a. Using the simulator and the *Base Configuration*, compute how many clock cycles take the program to execute.
- 2) Using the WinMIPS64 simulator, validate experimentally the Amdahl's law, defined as follows:

$$\text{speedup}_{\text{overall}} = \frac{\text{execution time}_{\text{old}}}{\text{execution time}_{\text{new}}} = \frac{1}{(1 - \text{fraction}_{\text{enhanced}}) + \frac{\text{fraction}_{\text{enhanced}}}{\text{speedup}_{\text{enhanced}}}}$$

- a. Using the program developed before: **program_2.s**
- b. Modify the processor architectural parameters related with multicycle instructions (Menu→Configure→Architecture) in the following way:

- 1) Configuration 1
 - Starting from the *Base Configuration*, change only the FP addition latency to 3
- 2) Configuration 2
 - Starting from the *Base Configuration*, change only the Multiplier latency to 4
- 3) Configuration 1
 - Starting from the *Base Configuration*, change only the division latency to 12

Compute by hand (using the Amdahl's Law) and using the simulator the speed-up for any one of the previous processor configurations. Compare the obtained results and complete the following table.

Table 1: **program_2.s** speed-up computed by hand and by simulation

Proc. Config.	Base config. [c.c.]	Config. 1	Config. 2	Config. 3
Speed-up comp.				
By hand	1386	1.069	1.095	1.351
By simulation	1386	1.045	1.095	1.351

- 3) Write an assembly program (**program_3.s**) for the winMIPS64 architecture able to compute the hamming distance between two consecutive elements of a data array X[] previously allocated in memory (the array X contains 30 8-bit elements). Given two consecutive elements X[i] and X[i+1], the Hamming distance is defined as the number of bits set to 1 in $(X[i] \oplus X[i+1])$.

If the Hamming distance is:

- even, the variable `even_counter` must be incremented
- odd, the variable `odd_counter` must be incremented

These two variables are allocated in memory and initially empty.

- 4) Considering the following *winMIPS64* architecture:
 - Code address bus: 12
 - Data address bus: 12
 - Pipelined FP arithmetic unit (latency): 4 stages
 - Pipelined multiplier unit (latency): 8 stages
 - divider unit (latency): not pipelined unit, 12 clock cycles
 - Forwarding is enabled
 - Branch prediction is disabled
 - Branch delay slot is disabled
 - *Integer ALU: 1 clock cycle*
 - *Data memory: 1 clock cycle*
 - *Branch delay slot: 1 clock cycle.*

- a. calculate by hand, how many clock cycles take the program to execute?

Number of clock cycles:	1484
-------------------------	------

- b. compute the same calculation using the *winMIPS64* simulator.

Number of clock cycles:	510
-------------------------	-----

Compare the results obtained in the points 4.a and 4.b., and provide some explanation in the case the results are different.

Eventual explanation:

La differenza del numero dei c.c. è dovuta ai salti condizionati: in alcuni cicli vengono eseguite meno istruzioni rispetto ad altri mentre nel calcolo a mano si è sempre considerato il “caso peggiore” (in cui vengono eseguite tutte le istruzioni, e quindi il numero di c.c. risulta più grande).

In particolare il numero di c.c. calcolati dalla simulazione dipende fortemente dall’input dato al programma.
